# ON $n$-PARTITE DIGRAPHICAL REPRESENTATIONS OF FINITE GROUPS 

JIA-LI DU, YAN-QUAN FENG*, AND PABLO SPIGA*

#### Abstract

A group $G$ admits an n-partite digraphical representation if there exists a regular $n$-partite digraph $\Gamma$ such that the automorphism group $\operatorname{Aut}(\Gamma)$ of $\Gamma$ satisfies the following properties: (1) $\operatorname{Aut}(\Gamma)$ is isomorphic to $G$, (2) Aut $(\Gamma)$ acts semiregularly on the vertices of $\Gamma$ and (3) the orbits of $\operatorname{Aut}(\Gamma)$ on the vertex set of $\Gamma$ form a partition into $n$ parts giving a structure of $n$-partite digraph to $\Gamma$. In this paper, for every positive integer $n$, we classify the finite groups admitting an $n$-partite digraphical representation.

Keywords: Semiregular group, regular representation, DRR, DnSR, $n$-PDR.
2010 Mathematics Subject Classification: 05C25, $20 B 25$.

## 1. Introduction

We start by summarising some basic definitions. A digraph $\Gamma$ is an ordered pair $(V \Gamma, A \Gamma)$, where $V \Gamma$ is a non-empty set and $A \Gamma$ is a subset of $V \Gamma \times V \Gamma$. It is customary to refer to $V \Gamma$ and to $A \Gamma$ as the vertex set and the arc set of $\Gamma$, respectively, and to refer to their elements as vertices and arcs. Given an $\operatorname{arc}(u, v) \in A \Gamma, v$ is an out-neighbour of $u$ and $u$ is an in-neighbour of $v$. The out-valency and the in-valency of $v \in V \Gamma$ is the number of out-neighbours and the number of in-neighbours of $v$. Moreover, $\Gamma$ is regular if there exists a non-negative integer $d$ such that every vertex $v \in V \Gamma$ has out-valency and in-valency $d$. Given a subset $X$ of $V \Gamma$, we denote by $\Gamma[X]:=(V \Gamma \cap X, A \Gamma \cap(X \times X))$ the sub-digraph induced by $\Gamma$ on $X$.

The digraph $\Gamma$ is a $\boldsymbol{g r a p h}$ if $A \Gamma$ is symmetric, that is, $A \Gamma=\{(u, v) \mid(v, u) \in A \Gamma\}$.
An automorphism of $\Gamma$ is a permutation $\sigma$ of $V \Gamma$ such that, for every $(u, v) \in V \Gamma \times V \Gamma$, $\left(u^{\sigma}, v^{\sigma}\right) \in A \Gamma$ if and only if $(u, v) \in A \Gamma$. The automorphism group $\operatorname{Aut}(\Gamma)$ of $\Gamma$ is the set of all automorphisms of $\Gamma$ and it is indeed a group under composition of permutations.

Let $G$ be a permutation group on a set $\Omega$ and let $\omega \in \Omega$. We let $G_{\omega}$ denote the stabiliser of $\omega$ in $G$, that is, the subgroup of $G$ fixing $\omega$. We say that $G$ is semiregular if $G_{\omega}=1$ for every $\omega \in \Omega$, and regular if it is semiregular and transitive. We denote by $\mathbb{Z}_{k}$ the cyclic group of order $k \in \mathbb{N} \backslash\{0\}$ and by $Q_{8}$ the quaternion group of order 8 .

We are now ready to give the definition of the main player in this paper. Let $G$ be a group and let $n$ be a positive integer. An $n$-partite digraphical representation ( $n$-PDR for short) of $G$ is a digraph $\Gamma=(V \Gamma, A \Gamma)$ such that

- $\Gamma$ is regular,
- $\operatorname{Aut}(\Gamma)$ is isomorphic to $G$,
- Aut $(\Gamma)$ acts semiregularly on $V \Gamma$,
- Aut $(\Gamma)$ has $n$ orbits on $V \Gamma$ and, for every orbit $X$, the sub-digraph $\Gamma[X]$ induced by $\Gamma$ on $X$ is the empty graph.
Observe that the last condition implies that $\Gamma$ is $n$-partite. The scope of this paper is to classify finite groups admitting $n$-PDRs.

[^0]Theorem 1.1. Let $G$ be a finite group and let $n$ be a positive integer. Then $G$ admits no $n$-partite digraphical representation if and only if one of the following occurs:
(1) $n=1$ and $|G| \geq 3$,
(2) $n=2$ and $G \cong \mathbb{Z}_{1}, \mathbb{Z}_{2}, \mathbb{Z}_{3}, \mathbb{Z}_{2} \times \mathbb{Z}_{2}$ or $\mathbb{Z}_{2} \times \mathbb{Z}_{2} \times \mathbb{Z}_{2}$;
(3) $3 \leq n \leq 5$ and $G \cong \mathbb{Z}_{1}$.

We now discuss the roots of our interest on Theorem 1.1. The study of group representations on digraphs starts with the classical work on DRRs. A digraphical regular representation of $G$ is a digraph $\Gamma=(V \Gamma, A \Gamma)$ such that $\operatorname{Aut}(\Gamma) \cong G$ and $\operatorname{Aut}(\Gamma)$ is regular on $V \Gamma$. Babai $\mathbb{1}$ has proved that, except for

$$
Q_{8}, \mathbb{Z}_{2} \times \mathbb{Z}_{2}, \mathbb{Z}_{2} \times \mathbb{Z}_{2} \times \mathbb{Z}_{2}, \mathbb{Z}_{2} \times \mathbb{Z}_{2} \times \mathbb{Z}_{2} \times \mathbb{Z}_{2} \text { and } \mathbb{Z}_{3} \times \mathbb{Z}_{3}
$$

every finite group admits a DRR. This classification plays a crucial role in our work. Observe that the case $n=1$ in Theorem 1.1 is trivial. Indeed, the last condition in the definition of $n$-PDR implies and a $1-\mathrm{PDR}$ is an empty graph. Therefore, a group having order at least 3 does not admit a 1-PDR, whereas $\mathbb{Z}_{1}$ and $\mathbb{Z}_{2}$ do admit a 1-PDR.

After the classification of finite groups admitting a DRR was completed, researchers proposed and investigated various natural generalisations. For instance, Babai and Imrich [2] classified finite groups admitting a tournament regular representation. Morris and Spiga [13, 14, 15], answering a question of Babai [1], classified the finite groups admitting an oriented regular representation. For more results, generalising DRRs in various directions, we refer to [7, 8, 9, 12, 16, 18]. To give some more context to Theorem [1.1, we give details to two more particular generalisations.

Given a positive integer $n$, a digraphical n-semiregular representation ( $\mathrm{D} n \mathrm{SR}$ for short) of $G$ is a regular digraph $\Gamma=(V \Gamma, A \Gamma)$ such that $\operatorname{Aut}(\Gamma) \cong G$ is semiregular on $V \Gamma$ with $n$ orbits. Observe that every $n$-PDR is also a $\mathrm{D} n \mathrm{SR}$, but not every $\mathrm{D} n \mathrm{SR}$ is necessarily a $n$-PDR because it may not be $n$-partite. Therefore, Theorem 1.1 can be seen as an extension of the classification in [8] of the finite groups admitting a DnSR. The second generalisation we discuss is concerned with Haar digraphs. Given a group $G$, a Haar digraph $\Gamma$ over $G$ is a bipartite digraph having a bipartition $\{X, Y\}$ such that $G$ is a group of automorphisms of $\Gamma$ acting regularly on $X$ and on $Y$. We say that $\Gamma$ is a Haar digraphical representation (HDR for short) of $G$, if there exists a regular Haar digraph over $G$ such that its automorphism group is isomorphic to $G$. We have proved in [11] that, except for

$$
\mathbb{Z}_{1}, \mathbb{Z}_{2}, \mathbb{Z}_{3}, \mathbb{Z}_{2} \times \mathbb{Z}_{2} \text { and } \mathbb{Z}_{2} \times \mathbb{Z}_{2} \times \mathbb{Z}_{2}
$$

every finite group admits a HDR. Observe that a digraph $\Gamma$ is a HDR of $G$ if and only if $\Gamma$ is a 2-PDR of $G$. Therefore, $n$-PDRs offer also a natural generalisation of HDRs. Furthermore, the classification in [11] of finite groups not admitting HDRs gives a classification of finite groups not admitting 2-PDRs. In particular, Theorem 1.1 (2) follows from [11. Thus, in the proof of Theorem 1.1, we may suppose that

$$
\begin{equation*}
n \geq 3 \tag{1.1}
\end{equation*}
$$

Despite the natural argument used by Babai for the classification of finite groups admitting a DRR, the classification of finite groups admitting a GRR has required considerable more work. Indeed, as a rule-of-thumb, representation results dealing with undirected graphs are difficult. For instance, we classify the finite groups $G$ having an abelian subgroup $A$ of index 2 admitting a bipartite DRR having bipartition $\{A, G \backslash A\}$. The analogous classification for Cayley graphs is much harder, see [9, 10]. In fact, we do not have a classification of finite groups admitting a Haar graphical representation and hence we have no classification of finite groups admitting an $n$-partite graphical representation, when $n \geq 2$. Incidentally, the case $n=2$ is in our opinion the most important. In this context, we believe that the classification of finite groups admitting a bipartite regular representation can be of some relevance, see the introductory section in 9 for more details.

We conclude this section observing that the work of Grech and Kisielewicz [4, 5, 6, which in spirit is trying to give an explicit description of some classes of permutation groups that are 2-closed, does fit within the subject of group representations on digraphs. In particular, some of the results of Grech and Kisielewicz are interesting in the context of DRRs and their generalisations.

## 2. Preliminaries and notations

Let $n$ be a positive integer and let $G$ be a finite group. Consistently throughout the whole paper, for not making our notation too cumbersome to use, we denote the element $(g, i)$ of the cartesian product $G \times\{0, \ldots, n-1\}$ simply by $g_{i}$. We often identify $\{0, \ldots, n-1\}$ with $\mathbb{Z}_{n}$, that is, with the integers modulo $n$.

For every $i, j \in \mathbb{Z}_{n}$, let $T_{i, j}$ be a subset of $G$. The $n$-Cayley digraph of $G$ with respect to $\left(T_{i, j}: i, j \in \mathbb{Z}_{n}\right)$ is the digraph with vertex set

$$
G \times \mathbb{Z}_{n}=\bigcup_{i \in \mathbb{Z}_{n}} G_{i}
$$

where $G_{i}=\left\{g_{i} \mid g \in G\right\}$, and with arc set

$$
\bigcup_{i, j}\left\{\left(g_{i},(t g)_{j}\right) \mid t \in T_{i, j}, g \in G\right\} .
$$

We denote this digraph by

$$
\operatorname{Cay}\left(G, T_{i, j}: i, j \in \mathbb{Z}_{n}\right)
$$

Observe that, when $n:=1$, 1-Cayley digraphs are nothing more and nothing less than Cayley digraphs. Similarly, when $n:=2$, 2-Cayley digraphs are also known as BiCayley digraphs in the literature. When dealing with Cayley digraphs, we omit the subscript, that is, we denote the Cayley digraph of $G$ with connection set $S$ with Cay $(G, S)$.

Set $\Gamma:=\operatorname{Cay}\left(G, T_{i, j}: i, j \in \mathbb{Z}_{n}\right)$. For every $g \in G$, the mapping

$$
\begin{aligned}
R_{n}(g): V \Gamma & \rightarrow V \Gamma \\
x_{i} & \mapsto(x g)_{i}
\end{aligned}
$$

is an automorphism of $\Gamma$. Thus $\left\{R_{n}(g) \mid g \in G\right\}$ is a subgroup of $\operatorname{Aut}(\Gamma)$ isomorphic to $G$. Since we are not interested in $G$ as an abstract group, but rather as a group of automorphisms of digraphs, for convenience, we identify $\left\{R_{n}(g) \mid g \in G\right\}$ with $G$. Observe that

- $G$ acts semiregularly on $V \Gamma=G \times \mathbb{Z}_{n}$,
- $G$ has $n$ orbits on $V \Gamma$ and these are $G_{i}$, with $i \in \mathbb{Z}_{n}$.

It is easy to see that a digraph $\Delta$ is an $n$-Cayley digraph of $G$ if and only if $\operatorname{Aut}(\Delta)$ contains a semiregular subgroup isomorphic to $G$ and with $n$ orbits on $V \Delta$. (When $n:=1$, this is a classic observation of Sabidussi [17, Lemma 4]; for the proof of the general case, it suffices to follow the argument of Sabidussi as a crib.)

In our work we need the following two results concerning DRRs: Proposition 2.1 is the classification of Babai [1, Theorem 2.1] of finite groups admitting a DRR which we mentioned in the introduction, Proposition 2.2 is a technical result proved in [11, Lemma 3.5].
Proposition 2.1. A finite group $G$ admits a DRR if and only if $G$ is not isomorphic to one of the following five groups: $Q_{8}, \mathbb{Z}_{2}^{2}, \mathbb{Z}_{2}^{3}, \mathbb{Z}_{2}^{4}$ and $\mathbb{Z}_{3}^{2}$.

Proposition 2.2. Let $G$ be a finite group of order at least 4 admitting a DRR. Then $G$ has a subset $R$ such that $\operatorname{Cay}(G, R)$ is a DRR, where $1 \notin R$ and $|R|<(|G|-1) / 2$.

Let $\Gamma:=\operatorname{Cay}\left(G, T_{i, j}: i, j \in \mathbb{Z}_{n}\right)$ be an $n$-Cayley digraph of $G$ with

$$
T_{i, i}=\emptyset, \forall i \in \mathbb{Z}_{n} .
$$

Then, for every $i \in \mathbb{Z}_{n}, \Gamma\left[G_{i}\right]$ is the empty graph. Thus $\Gamma$ is an $n$-partite digraph where every part is an orbit of $G$. We call these digraphs n-partite Cayley digraphs. Summing up, a group $G$ admits an $n$-PDR if and only if $G$ admits a regular $n$-partite Cayley digraph having $G$ as its automorphism group.

As we mentioned in the introduction, a regular 2-partite Cayley digraph of $G$ is also called Haar digraph of $G$ (see [11]). Moreover, since $T_{0,0}=T_{1,1}=\emptyset$, it can be written as $\operatorname{Cay}\left(G, T_{0,1}, T_{1,0}\right)$.

In our work we need the following two results concerning 2-PDRs (a.k.a. HDRs, for Haar digraphical representations): Proposition [2.3 is the classification of finite groups admitting a HDR [11, Theorem 1.1], Proposition [2.4 is a technical result whose proof follows from the proof of Lemma 3.4 and Theorem 1.1 in [11.

Proposition 2.3. A finite group $G$ admits a 2-PDR if and only if $G$ is not isomorphic to one of the following five groups: $\mathbb{Z}_{1}, \mathbb{Z}_{2}, \mathbb{Z}_{3}, \mathbb{Z}_{2}^{2}$ and $\mathbb{Z}_{2}^{3}$.
Proposition 2.4. Let $G$ be a finite group and let $\operatorname{Cay}(G, R)$ be a $\operatorname{DRR}$ of $G$, where $1 \notin R \subset G$ and $|R|<|G| / 2$. Then $G$ has a subset $L$ such that $\operatorname{Cay}(G, R \cup\{1\}, L \cup\{1\})$ is a 2-PDR, where $L \subseteq G \backslash\left(R^{-1} \cup\{1\}\right)$ and $|L|=|R|$.

We conclude this section with some results concerning small troublesome groups.
Lemma 2.5. The following hold:
(1) $\mathbb{Z}_{1}$ admits an $n$-PDR if and only if $n=1$ or $n \geq 6$,
(2) $\mathbb{Z}_{1}$ admits an $n$-PDR if and only if $n=1$ or $n \geq 3$,
(3) $\mathbb{Z}_{3}$ admit an $n$-PDR if and only if $n \geq 3$.

Proof. We start by dealing with $\mathbb{Z}_{1}$. Observe that over $\mathbb{Z}_{1}, n$-PDRs and DnSRs define the same family of digraphs. Now, by [8, Theorem $1.2(4)], \mathbb{Z}_{1}$ admits a $\operatorname{D} n \mathrm{SR}$ if and only if $n=1$ or $n \geq 6$. Thus part (1) immediately follows.

From (1.1), $n \geq 3$. Let $G$ be either $\mathbb{Z}_{2}$ or $\mathbb{Z}_{3}$, let $a$ be a generator of $G$ and let

$$
\begin{aligned}
T_{i, i+1} & =T_{i+1, i}:=\{1\}, \text { when } i \in \mathbb{Z}_{n} \backslash\{1\}, \\
T_{2,1} & =T_{1,2}:=\{a\}, \\
T_{j, k} & :=\emptyset, \quad \text { otherwise. }
\end{aligned}
$$

Let $\Gamma:=\operatorname{Cay}\left(G, T_{i, j}: i, j \in \mathbb{Z}_{n}\right)$ and let $A:=\operatorname{Aut}(\Gamma)$. See Figure 1 for a rough drawing of $\Gamma$. Clearly, $\Gamma$ is a regular $n$-partite Cayley digraph for $G$. Therefore, to finish the proof, we only need to show that $A=G$. To do that, we use the fact that,
$(\dagger) \quad$ there is a unique undirected path from $1_{1}$ to $1_{2}$ of length $n-1$ (namely, the path $1_{1}, 1_{0}, 1_{n-1}, 1_{n-2}, \ldots, 1_{3}, 1_{2}$ ), whereas, there is no such path from $1_{2}$ to $a_{1}$.
Observe now that

- $\Gamma\left[G_{1} \cup G_{2}\right]$ is a directed cycle of length four when $G \cong \mathbb{Z}_{2}$ and of length six when $G \cong \mathbb{Z}_{3}$ (every arc on the cycle is a directed edge),
- for $i \in \mathbb{Z}_{n} \backslash\{1\}, \Gamma\left[G_{i} \cup G_{i+1}\right]$ is a perfect matching,
- in all other cases, $\Gamma\left[G_{j} \cup G_{k}\right]$ is the empty graph.

See again Figure 1 . Thus, $A$ fixes $G_{1} \cup G_{2}$ setwise. In particular, $A$ induces a group of automorphisms of the directed cycle $\Gamma\left[G_{1} \cup G_{2}\right]$. Therefore, $\left\{G_{1}, G_{2}\right\}$ is a system of imprimitivity for the (not necessarily transitive) action of $A$ on $G_{1} \cup G_{2}$.

Suppose $A$ does not fix setwise $G_{1}$. As $G \leq A$ and as $G$ acts transitively on $G_{1}$ and on $G_{2}$, there exists $\alpha \in A$ with $1_{1}^{\alpha}=1_{2}$. Since $\left(1_{1}, 1_{2}\right)$ is an arc of $\Gamma\left[G_{1} \cup G_{2}\right],\left(1_{1}, 1_{2}\right)^{\alpha}=\left(1_{1}^{\alpha}, 1_{2}^{\alpha}\right)=\left(1_{2}, 1_{2}^{\alpha}\right)$ is also an arc of $\Gamma\left[G_{1} \cup G_{2}\right]$ and hence $1_{2}^{\alpha}=a_{1}$. However, this contradicts ( $\dagger$ ). Thus $A$ fixes $G_{1}$ and $G_{2}$ setwise. Since $G$ acts transitively on $G_{2}$, from the Frattini argument, we have $A=G A_{1_{2}}$. Now, as $\Gamma\left[G_{1} \cup G_{2}\right]$ is a directed cycle, it follows easily that $A_{1_{2}}$ fixes $G_{1}$ and $G_{2}$ pointwise.

Figure 1. $n$-PDRs for $\mathbb{Z}_{2}$ and $\mathbb{Z}_{3}$ with $n \geq 3$
Since $\Gamma\left[G_{2} \cup G_{3}\right]$ is a perfect matching, $A_{1_{2}}$ fixes $G_{3}$ pointwise, and arguing inductively, $A_{1_{2}}$ fixes $G_{i}$ pointwise for every $i \in \mathbb{Z}_{n}$. It follows $A_{1_{2}}=1$ and $A=G A_{1_{2}}=G$.
Lemma 2.6. The groups $\mathbb{Z}_{2}^{2}$ and $\mathbb{Z}_{2}^{3}$ admit an $n-\mathrm{PDR}$ if and only $n \geq 3$.
Proof. From (1.1), $n \geq 3$. Suppose first $G \cong \mathbb{Z}_{2}^{2}$. Let $a, b \in G$ with $G=\langle a\rangle \times\langle b\rangle$ and let

$$
\begin{aligned}
T_{i, i+1} & =T_{i+1, i}:=\{1\}, \text { when } i \in \mathbb{Z}_{n} \backslash\{0,1\}, \\
T_{0,1} & :=\{1\}, T_{1,0}:=\{a\}, T_{1,2}:=\{b\}, T_{2,1}:=\{a\}, \\
T_{j, k} & :=\emptyset, \text { otherwise. }
\end{aligned}
$$

Let $\Gamma:=\operatorname{Cay}\left(G, T_{i, j}: i, j \in \mathbb{Z}_{n}\right)$ and let $A:=\operatorname{Aut}(\Gamma)$. See Figure 2 for a rough drawing of $\Gamma$. Clearly, $\Gamma$ is a regular $n$-partite Cayley digraph of $G$. To finish the proof, we only need to show that $A=G$.

Figure 2. $n$-PDRs for $\mathbb{Z}_{2}^{2}$ with $n \geq 3$
By Figure 2, for every $g_{1} \in G_{1}, g_{1}$ is incident to no undirected edge of $\Gamma$; however, for $i \in \mathbb{Z}_{n} \backslash\{1\}$, for every $g_{i} \in G_{i}, g_{i}$ is incident to at least one undirected edge of $\Gamma$. Thus, $A$ fixes $G_{1}$ setwise. Furthermore,

- $\Gamma\left[G_{i} \cup G_{i+1}\right]$ is a perfect matching, for every $i \in \mathbb{Z}_{n} \backslash\{0,1\}$,
- $\Gamma\left[G_{0} \cup G_{1}\right]$ and $\Gamma\left[G_{1} \cup G_{2}\right]$ are both union of two directed cycles of length 4 , and
- in all other cases, $\Gamma\left[G_{j} \cup G_{k}\right]$ is the empty graph.

Thus, $A$ fixes $G_{1}$ and $G_{0} \cup G_{2}$ setwise.
Suppose $A$ does not fix setwise $G_{0}$. Then, there exists $\alpha \in A$ with $1_{0}^{\alpha}=1_{2}$. Observe that $1_{0}, 1_{n-1}, 1_{n-2}, \ldots, 1_{2}$ is the unique undirected path of length $n-2$ passing through $1_{0}$, and also the unique undirected path of length $n-2$ passing through $1_{2}$. Then $1_{0}^{\alpha}=1_{2}$ implies $1_{2}^{\alpha}=1_{0}$, that is, $\alpha$ interchanges $1_{0}$ and $1_{2}$. Using Figure 2, it is readily seen that $\alpha$ interchanges the two directed cycles $\left(1_{0}, 1_{1}, a_{0}, a_{1}\right)$ and $\left(1_{2}, a_{1},(a b)_{2}, b_{1}\right)$, that is,

$$
\begin{aligned}
\left(1_{2}, a_{1},(a b)_{2}, b_{1}\right) & =\left(1_{0}, 1_{1}, a_{0}, a_{1}\right)^{\alpha}=\left(1_{0}^{\alpha}, 1_{1}^{\alpha}, a_{0}^{\alpha}, a_{1}^{\alpha}\right)=\left(1_{2}, 1_{1}^{\alpha}, a_{0}^{\alpha}, a_{1}^{\alpha}\right) \\
\left(1_{0}, 1_{1}, a_{0}, a_{1}\right) & =\left(1_{2}, a_{1},(a b)_{2}, b_{1}\right)^{\alpha}=\left(1_{2}^{\alpha}, a_{1}^{\alpha},(a b)_{2}^{\alpha}, b_{1}^{\alpha}\right)=\left(1_{0}, a_{1}^{\alpha},(a b)_{2}^{\alpha}, b_{1}^{\alpha}\right) .
\end{aligned}
$$

Thus $1_{1}=a_{1}^{\alpha}=b_{1}$, which is a contradiction. Thus, $A$ fixes $G_{0}$ and $G_{2}$ setwise. Since $G$ is transitive on $G_{0}$, from the Frattini argument, we have $A=G A_{1_{0}}$. Moreover, now that we know that $A_{1_{0}}$ fixes setwise $G_{0}, G_{1}$ and $G_{2}$, it is easy to see that $A_{1_{0}}$ fixes $G_{0}, G_{1}$ and $G_{2}$ pointwise, because $A_{1_{0}}$ fixes all directed cycles in $\Gamma\left[G_{0} \cup G_{1}\right] \cup \Gamma\left[G_{1} \cup G_{2}\right]$. Since $\Gamma\left[G_{2} \cup G_{3}\right]$ is a perfect matching, $A_{1_{0}}$ fixes $G_{3}$ pointwise, and arguing inductively, $A_{1_{0}}$ fixes $G_{i}$ pointwise for every $i \in \mathbb{Z}_{n}$. It follows that $A=G A_{1_{0}}=G$, that is, $\Gamma$ is an $n$-PDR.

We now consider the case $G \cong \mathbb{Z}_{2}^{3}$. Let $a, b, c \in G$ with $G=\langle a\rangle \times\langle b\rangle \times\langle c\rangle$ and let

$$
\begin{aligned}
T_{i, i+1} & =T_{i+1, i}:=\{1\}, \text { when } i \in \mathbb{Z}_{n} \backslash\{0,1\}, \\
T_{0,1} & :=\{a\}, T_{1,0}:=\{b\}, T_{1,2}:=\{a\}, T_{2,1}:=\{c\}, \\
T_{j, k} & :=\emptyset, \text { otherwise. }
\end{aligned}
$$

Let $\Gamma=\operatorname{Cay}\left(G, T_{i, j}: i, j \in \mathbb{Z}_{n}\right)$ and let $A=\operatorname{Aut}(\Gamma)$. As usual, we have drawn $\Gamma$ in Figure 3, Then $\Gamma$ is a regular $n$-partite Cayley digraph of $G$.

Figure 3. $n$-PDRs for $\mathbb{Z}_{2}^{3}$ with $n \geq 3$
It is readily seen that

- $\Gamma\left[G_{0} \cup G_{1}\right]$ and $\Gamma\left[G_{1} \cup G_{2}\right]$ are both a union of four directed cycles of length 4,
- $\Gamma\left[G_{i} \cup G_{i+1}\right]$ is a perfect matching for every $i \in \mathbb{Z}_{n} \backslash\{0,1\}$, and
- in all other cases, $\Gamma\left[G_{j} \cup G_{k}\right]$ is the empty graph.

From this, it follows that $A$ fixes $G_{1}$ and $G_{0} \cup G_{2}$ setwise. Note that, if $\alpha \in A$ interchanges $1_{0}$ and $1_{2}$, then it interchanges the directed cycles $\left(1_{0}, a_{1},(a b)_{0},(a b)_{1}\right)$ and $\left(1_{2}, c_{1},(a c)_{2}, a_{1}\right)$, which is
impossible. Then, arguing as in the case $G \cong \mathbb{Z}_{2}^{2}$, we obtain that $A_{1_{0}}$ fixes each of $G_{0}, G_{1}$ and $G_{2}$ setwise. Using Figure 3, we see that the only automorphism of $\Gamma\left[G_{0} \cup G_{1}\right] \cup \Gamma\left[G_{1} \cup G_{2}\right]$ fixing setwise $G_{0}, G_{1}$ and $G_{2}$ and fixing $1_{0}$ is the identity. Therefore $A_{1_{0}}$ fixes $G_{0} \cup G_{1} \cup G_{2}$ pointwise. From this it follows that $A_{1_{0}}$ fixes $G_{i}$ pointwise, for every $i \in \mathbb{Z}_{n}$. Thus $A=G A_{1_{0}}=G$ and $\Gamma$ is an $n$-PDR of $G$.

## 3. Proof of Theorem 1.1

In this section, we prove Theorem 1.1 and, to do that, we need one more auxiliary result.
Lemma 3.1. If the finite group $G$ admits a 2-PDR, then $G$ admits an $n$-PDR for every $n \geq 2$.
Proof. Let $G$ be a finite group admitting a 2-PDR. By Proposition 2.3,

$$
\begin{equation*}
G \not \equiv \mathbb{Z}_{1}, \mathbb{Z}_{2}, \mathbb{Z}_{2}^{2}, \mathbb{Z}_{2}^{3} \text { and } \mathbb{Z}_{3} . \tag{3.1}
\end{equation*}
$$

In particular, $|G| \geq 4$. We consider two cases in turn: first $G$ admits a DRR, then $G$ admits no DRR.

Case 1: $G$ admits a DRR.
By Propositions 2.2 and [2.4, $G$ has subsets $R$ and $L$ such that $\operatorname{Cay}(G, R)$ is a $\operatorname{DRR}$ and $\operatorname{Cay}(G, R \cup$ $\{1\}, L \cup\{1\})$ is a 2-PDR, where $1 \notin R,|R|<(|G|-1) / 2, L \subseteq G \backslash\left(R^{-1} \cup\{1\}\right)$ and $|L|=|R|$. We now divide the proof in two further cases, depending on whether $G$ is an elementary abelian 2-group or not.
Case 1.1: $G$ is an elementary abelian 2-group.
Since $\operatorname{Cay}(G, R)$ is a $\operatorname{DRR}$ and $|G|>2, \operatorname{Cay}(G, R)$ is connected and hence $G=\langle R\rangle$. In particular, $|R| \geq 2$. From (3.1), we have $G \cong \mathbb{Z}_{2}^{k}$ with $k \geq 4$ and, since $|R|<(|G|-1) / 2, G$ has a non-identity element $b \in G \backslash R$. Let $\Gamma$ be the $n$-Cayley digraph $\operatorname{Cay}\left(G, T_{i, j}: i, j \in \mathbb{Z}_{n}\right)$, where

$$
\begin{align*}
T_{i, i+1} & :=R \cup\{1\} \text { for } i \in \mathbb{Z}_{n} ; T_{1,0}:=L \cup\{1\}, T_{i+1, i}:=R \cup\{b\} \text { for } i \in \mathbb{Z}_{n} \backslash\{0\} ;  \tag{3.2}\\
T_{j, k} & :=\emptyset \text { for } j, k \in \mathbb{Z}_{n} \text { with } j \neq k \pm 1 . \tag{3.3}
\end{align*}
$$

It is readily seen that $\Gamma$ is a regular $n$-partite Cayley digraph. To prove that $\Gamma$ is an $n$ - PDR , it suffices to show that $A:=\operatorname{Aut}(\Gamma)=G$. Note that $R=R^{-1}$ and $L=L^{-1}$, because $G$ is an elementary abelian 2-group.

Let $i, j \in \mathbb{Z}_{n}$. Observe that,

- when $i \neq j \pm 1, \Gamma\left[G_{i} \cup G_{j}\right]$ is the empty graph (this follows from (3.3)),
- every vertex in $\Gamma\left[G_{0} \cup G_{1}\right]$ is adjacent to only one undirected edge (this follows from (3.2), because $T_{0,1}^{-1} \cap T_{1,0}=\{1\}$ ),
- when $i \neq 0$, every vertex in $\Gamma\left[G_{i} \cup G_{i+1}\right]$ is adjacent to $|R|$ undirected edges (this follows from (3.2), because $T_{i, i+1}^{-1} \cap T_{i+1, i}=R$ ).
It follows that every vertex in $G_{0}$ and $G_{1}$ is incident to $|R|+1$ undirected edges and, when $i \in \mathbb{Z}_{n} \backslash$ $\{0,1\}$, every vertex in $G_{i}$ is incident to $2|R|$ undirected edges. Since $|R| \geq 2$, we have $|R|+1 \neq 2|R|$ and hence $A$ fixes $G_{0} \cup G_{1}$ setwise. Therefore $A$ induces a group of automorphisms on $\Gamma\left[G_{0} \cup G_{1}\right]$.

Note that

$$
\Gamma\left[G_{0} \cup G_{1}\right]=\operatorname{Cay}\left(G, T_{0,1}, T_{1,0}\right)=\operatorname{Cay}(G, R \cup\{1\}, L \cup\{1\}) .
$$

Since $\operatorname{Cay}(G, R \cup\{1\}, L \cup\{1\})$ is a 2-PDR, the automorphism group of $\Gamma\left[G_{0} \cup G_{1}\right]$ is $G$ and hence $A$ fixes $G_{0}$ and $G_{1}$ setwise and $A_{1_{0}}$ fixes $G_{0}$ and $G_{1}$ pointwise.

From (3.2), $T_{1,2}^{-1} \cap T_{2,1}=R$ and $T_{1,2}=R \cup\{1\}$. It follows that, for every $g_{1} \in G_{1}$, there exists a unique $h_{2} \in G_{2}$ such that $\left(g_{1}, h_{2}\right)$ is an arc of $\Gamma\left[G_{1} \cup G_{2}\right]$ and $\left(h_{1}, g_{2}\right)$ is not an arc of $\Gamma$. From this observation and from the fact that $A_{1_{0}}$ fixes $G_{1}$ pointwise, we have that $A_{1_{0}}$ fixes $G_{2}$ pointwise. Now, when $3 \leq i \leq n-1$, as $T_{i, i+1}=R \cup\{1\}$ and $T_{i+1, i}=R \cup\{b\}$, with an entirely
similar argument and with an elementary induction, we get that $A_{1_{0}}$ fixes $G_{i}$ pointwise. Therefore, $A_{1_{0}}=1$ and $A=G A_{1_{0}}=G$.
Case 1.2: $G$ is not an elementary abelian 2-group.
Let $a$ be an arbitrary element of $G$ having order $o$ at least 2 . Recall that $1 \notin R,|R|<(|G|-1) / 2$, $L \subseteq G \backslash\left(R^{-1} \cup\{1\}\right)$ and $|L|=|R|$. Thus, $|R|+|L|<|G|-1$. From this we deduce that $G$ has three subsets $S, W$ and $K$ such that

- $|S|=|R|+1$ with $1, a \in S$;
- $W \subseteq G \backslash S^{-1}$ with $|W|=|R|-1$,
- $K:=W \cup\left\{1, a^{-1}\right\}$.

Observe that $|R|+1=|L|+1=|S|=|K|$ and $S^{-1} \cap K=\left\{1, a^{-1}\right\}$. Set
$T_{0,1}:=R \cup\{1\}, T_{1,0}:=L \cup\{1\} ; T_{i, i+1}:=S, T_{i+1, i}:=K, T_{j, k}:=\emptyset, i, j, k \in \mathbb{Z}_{n}$ with $i \neq 0, j \neq k \pm 1$.
Let $\Gamma:=\operatorname{Cay}\left(G, T_{i, j}: i, j \in \mathbb{Z}_{n}\right)$ and let $A:=\operatorname{Aut}(\Gamma)$. Then $\Gamma$ is a regular $n$-partite Cayley digraph of $G$. Furthermore,

- when $i \neq j \pm 1, \Gamma\left[G_{i} \cup G_{j}\right]$ is the empty graph,
- when $i \neq 0$, every vertex in $\Gamma\left[G_{i} \cup G_{i+1}\right]$ has two undirected edge (because $T_{i, i+1} \cap T_{i+1, i}^{-1}=$ $\left.S \cap K^{-1}=\{1, a\}\right)$,
- every vertex in $\Gamma\left[G_{0} \cup G_{1}\right]$ has only one undirected edge (because $T_{0,1} \cap T_{1,0}^{-1}=\{1\}$ ).

It follows that every vertex in $G_{0}$ and $G_{1}$ is incident to 3 undirected edges and, when $i \in \mathbb{Z}_{n} \backslash\{0,1\}$, every vertex in $G_{i}$ is incident to 4 undirected edges. Thus, $A$ fixes $G_{0} \cup G_{1}$ setwise. Since $\Gamma\left[G_{0} \cup G_{1}\right]=$ $\operatorname{Cay}(G, R \cup\{1\}, L \cup\{1\})$ is a 2-PDR, $A$ fixes $G_{0}$ and $G_{1}$ setwise and $A_{1_{0}}$ fixes $G_{0}$ and $G_{1}$ pointwise.

Since $T_{1,2} \cap T_{2,1}^{-1}=\{1, a\}$, every vertex in $G_{1}$ has two undirected edges with the other ends in $G_{2}$ and, similarly, every vertex in $G_{2}$ has two undirected edges with the other ends in $G_{1}$. Therefore, all edges in $\Gamma\left[G_{1} \cup G_{2}\right]$ consist of cycles of length $2 o$. Since $o \geq 3$ and $A_{1_{0}}$ fixes $G_{1}$ pointwise, $A_{1_{0}}$ fixes $G_{2}$ pointwise. Similarly, since $T_{i, i+1} \cap T_{i+1, i}^{-1}=\{1, a\}$ for every $i \in \mathbb{Z}_{n} \backslash\{0\}$, we have that $A_{1_{0}}$ fixes $G_{i}$ pointwise for every $i \in \mathbb{Z}_{n}$. It follows that $A_{1_{0}}=1$ and $A=G A_{1_{0}}=G$, that is, $\Gamma$ is an $n$-PDR.

Case 2: $G$ admits no DRR.
Recall that $G \nsubseteq \mathbb{Z}_{1}, \mathbb{Z}_{2}, \mathbb{Z}_{2}^{2}, \mathbb{Z}_{2}^{3}$ and $\mathbb{Z}_{3}$. By Proposition 2.1, $G \cong \mathbb{Z}_{2}^{4}, Q_{8}$, or $\mathbb{Z}_{3}^{2}$. First we claim that $G$ has three subsets $R, L$ and $K$ such that

- $\operatorname{Cay}(G, R, L)$ is a $2-\mathrm{PDR}$,
- $\left|R \cap L^{-1}\right|=1$ and $|R|=|L| \geq 3$,
- $|K|=|R|=|L|$ and $\left|R \cap K^{-1}\right|=|R|-1$.

Indeed, when $G=\langle a\rangle \times\langle b\rangle \times\langle c\rangle \times\langle d\rangle \cong \mathbb{Z}_{2}^{4}$, take

$$
R:=\{1, a, b, c, d, a d\}, L:=\{1, a c, b c, a b c, a b d, b c d\} \text { and } K:=\{a b\} \cup\left(R^{-1} \backslash\{1\}\right),
$$

when $G=\left\langle a, b \mid a^{4}=b^{4}=1, b^{2}=a^{2}, a^{b}=a^{-1}\right\rangle \cong Q_{8}$, take

$$
R:=\{1, a, b\}, L:=\left\{a^{2}, b^{-1}, a b\right\} \text { and } K:=\{a b\} \cup\left(R^{-1} \backslash\{1\}\right),
$$

when $G=\langle a\rangle \times\langle b\rangle \cong \mathbb{Z}_{3}^{2}$, take

$$
R:=\{1, a, b\}, L:=\left\{a, b^{-1}, a b\right\} \text { and } K:=\{a b\} \cup\left(R^{-1} \backslash\{1\}\right) .
$$

Now, an elementary computation with the computer algebra system Magma [3] reveals that with these choices of $R, L$ and $K$ all three conditions above are satisfied.

To finish the proof, it suffices to show that $G$ admits an $n$-PDR for every $n \geq 3$. Set

$$
T_{0,1}:=R, T_{1,0}:=L ; T_{i, i+1}:=R, T_{i+1, i}:=K, T_{j, k}:=\emptyset, i, j, k \in \mathbb{Z}_{n} \text { with } i \neq 0, j \neq k \pm 1 .
$$

Let $\Gamma=\operatorname{Cay}\left(G, T_{i, j}: i, j \in \mathbb{Z}_{n}\right)$. Then every vertex in $\Gamma\left[G_{0} \cup G_{1}\right]$ is incident to exactly one undirected edge and, for $i \neq 0$, every vertex in $\Gamma\left[G_{i} \cup G_{i+1}\right]$ is incident to exactly $|R|$ undirected edges and one directed edge. This yields that the automorphism group of $\Gamma$ fixes setwise $G_{0} \cup G_{1}$. Now, to conclude the proof we argue as in Case 1.1 and we obtain that $\Gamma$ is an $n$-PDR.

Proof of Theorem 1.1. From (1.1), we have $n \geq 3$. To finish the proof, it suffices to show that $G$ admits no $n$-PDR if and only if $3 \leq n \leq 5$ and $G=\mathbb{Z}_{1}$.

The sufficiency follows from Lemma 2.5. To prove the necessity, by Lemma 3.1, we may assume that $G$ admits no 2-PDR. Now, by Proposition 2.3, $G \cong \mathbb{Z}_{1}, \mathbb{Z}_{2}, \mathbb{Z}_{2}^{2}, \mathbb{Z}_{2}^{3}$ or $\mathbb{Z}_{3}$. By Lemmas 2.5 and [2.6. $G \cong \mathbb{Z}_{1}$ and $3 \leq n \leq 5$.
